

1 Sistema a fase minima

Si consideri il seguente schema di controllo:

dove

$$G(s) = \frac{50}{(1+0.1s)(1+s)(1+10s)} \quad H(s) = \frac{5}{1+0.01s}$$

Si vuole progettare R(s) in modo tale che:

$$|e_{\infty}| \le 0.025$$
, $y^{\circ}(t) = 10 \operatorname{sca}(t)$
 $d(t) = \pm \operatorname{sca}(t)$
 $\omega_c \ge 1 \operatorname{rad/s}$
 $\varphi_m \ge 60^{\circ}$

2 Processo a fase non minima

Sia

$$G(s) = \frac{10(1-s)}{1+10s}$$

Specifiche:

$$|e_{y^{\circ},\infty}| = 0$$
, $y^{\circ}(t) = \text{sca}(t)$
 $|e_{n,\infty}| \leq \frac{1}{10}$, $n(t) = \sin(\omega_d t)$, $\omega_d \geq 10 \text{rad/s}$
 $\omega_c \geq 0.1 \text{ rad/s}$
 $\varphi_m \geq 40^{\circ}$

3 Sistema con ritardo

con

$$G(s) = \frac{e^{-s}}{(1+s)(1+10s)}$$

Specifiche:

$$|e_{\infty}| < 0.15, \quad d(t) = \pm \operatorname{sca}(t)$$

 $\omega_c \ge 0.3 \text{ rad/s}$
 $\varphi_m \ge 40^{\circ}$

4 Disturbi Fourier trasformabili

Per il seguente sistema di controllo:

in cui:

$$G(s) = \frac{2}{(1+s)(1+0.2s)}$$

Si progetti il regolatore R(s) in modo tale che:

$$|e_{\infty}| < 0.1, \quad y^{\circ}(t) = \text{ram}(t), \ d(t) = 0$$

 $A_y < 0.1, \quad d(t) = \sin(\omega_d t), \omega_d \le 0.2 \text{rad/s}$
 $\omega_c \ge 1 \text{ rad/s}$
 $\varphi_m \ge 40^{\circ}$

dove A_y indica l'ampiezza del segnale sinusoidale y(t) ottenuto a fronte del disturbo indicato a transitorio esaurito.
